AUTHORS: Britva, Ya.D., Zhukov, N.P., Zhurba, V.K., Pecherskiy, Ye.A.

TITLE: On the problem of pressing rate in die-casting machines

PERIODICAL: Liteynoye proizvodstvo, no. 1, 1963, 10 - 11

TEXT: To vary the pressing rate during die-casting, it is necessary to change over from the differential feed of the hydraulic fluid to the cylinder to the non-differential feed. An accurate determination of the change-over moment requires a device which measures the rate of pressing. A prototype model of a device determining the average speed of the plunger over a distance of at least 10 mm has been developed by the Novosibirsk "Siblitmash" Plant. The time intervals in which the plunger travels the necessary section of stroke are determined by two contact pickups which are mounted on the path of travel of the press plunger. The authors present a brief description of operation and a block diagram of the device. There are 2 figures. ✓

AUTHOR: Pecherskiy, Yu. N. and Utkin, A. A.

TITLE: Programming an analysis of relay circuits

PERIODICAL: Referativnyy zhurnal, Avtomatika, telemekhanika i vychislitel'naya
tekhnika, no. 4, 1963, 59, abstract 4A367 (Uch. zap. Tomskiy un-t;
1962, no. 41, 180-193)

TEXT: The task involved in analysis of a relay circuit is to determine the system of functions of the link of output and input logical variables (matrix of reactions) and to find the matrices of the transitions. It is noted that the process of analysis of relay circuits may be automated. As distinct from familiar methods based upon the construction of specialized devices, the method in question is based upon the use of universal digital computers. Here, the analysis of a relay circuit amounts to an analysis of N logical circuits, where N is the number of conditions. If we fix the values of the proper variables, then the relay circuit may be regarded as logical. By means of successive selections of all conditions of feedbacks, all unknown functions are determined. With the help of the given program, the authors analyze a number of logical and relay circuits. Here, the time of analysis of a logical circuit of 13 elements amounts to 8 minutes; of a

Programming an analysis

circuit of 19 elements, 11 minutes. To analyze a relay circuit of four elements with two feedback loops requires 20 minutes. The authors point out the advantages and weaknesses of the use of specialized and universal computers. There are four illustrations and a bibliography of 7 items. A. S.

Title : Influence of Chlorpormazine and Hexamethonium on Interoceptors

Orig Pub : Fiziol. norm. si patol., 1958, 5, No 1, 29-37

Abstract : The effect of hexamethonium and chlorpormazine on the interoceptors was studied on the intestines, kidneys and spleen of dogs perfused with a Tyrode solution, with intact nerve connections. The vasopressor and respiratory reflexes caused by the introduction of 2 ml of a 2% KCl solution were used as a test. It is shown that hexamethonium does not have any influence on the interoceptors, but chlorpormazine stops their excitability.

Title: Improvement of the Quality of Vodka by Purification with Potassium Ferrocyanide

Original

Periodical: Podobreniye na rakite posredstvom bystrene s kaliyev ferotsianid. Lozarstvo i vinarstvo, 1954, 3, No 2, 126-127; Bulgarian

Abstract: To remove the salts of heavy metals which impart to vodka an unpleasant metallic taste and opalescence it is proposed to treat vodka with potassium ferrocyanide (I). This is done by first adding tannin at a rate of 2-4 g per 100 l, then I, and thereafter gelatin, 2-4 g per 100 l. After 6-8 days the vodka is separated from the precipitate and filtered. Standing in contact with precipitate must not exceed 2 weeks. The treated vodka is analyzed for absence of unreacted I.

TITLE: Exchange Capacity of Aluminosilicate Cracking Catalysts

PERIODICAL: Zhurnal fizicheskoy khimii, 1960, Vol. 34, No. 10,
pp. 2217 - 2222

TEXT: Aluminosilicate catalysts used for the cracking of hydrocarbons have an acid character. The type of acid and the role of the various acids upon the catalytic process have hitherto not been clarified. V. A. Chernov (Ref. 7) showed that in montmorillonite alumina, besides proton exchange, also an exchange of aluminum ions is possible, and that alumina can be regarded as an aluminum salt of aluminosilicic acids. The present paper deals with the ion exchange of an aluminosilicate catalyst in aqueous salt solutions of alkali metals. A commercial catalyst (14.01%Al₂O₃, 84.66%SiO₂, 0.36%Na₂O, 0.13%Fe₂O₃, 0.60%CaO) with a specific surface of 305 m²/g was used, and annealed at 550°C for two hours before the experiment. The experiments were

Card 1/3

Exchange Capacity of Aluminosilicate
Cracking CatalystsS/076/60/034/010/007/022
B015/B064

conducted with NaCl, LiCl, and sodium acetate solutions of different concentrations. The acidity caused by the exchange of the alkali metal for the proton in the catalyst was determined by a method of V. A. Chernov (Ref. 8). The ion exchange was determined by potentiometric titration of the solutions (after two days' vigorous shaking with the catalyst). The results obtained show that the amount of the exchanged protons is much smaller than that of the aluminum ions. After the exchange reaction, aluminum was detected in the NaCl and LiCl solutions, while this was not the case with the sodium acetate solution. This is due to the fact that aluminum acetate hydrolyzes immediately on the surface of the catalyst where it is deposited as aluminum hydroxide, an equivalent amount of acetic acid being dissolved. Experiment and calculation show that the maximum amount of the hydrogen and aluminum ions of the catalyst exchanged by alkali metal ions is practically independent of the type of the latter (i.e., the values for Li and Na ions are practically equal). For the above reason, the amount of acetic acid forming from the sodium acetate solution during the exchange of the ions of the catalyst for Na ions corresponds to the sum of the equivalents of the exchanged hydrogen and aluminum ions of the catalyst. There are

TITLE: Volume packing of porous graphite materials with carbon

CITED SOURCE: Tr. Mosk. khim.-tekhnol. in-ta im. D. I. Mendeleeva, vy'p. 42, 1963, 35-38

TOPIC TAGS: graphite, graphite material, carbon, volume packing

TRANSLATION: To guarantee volume packing of porous graphite materials at a temperature of 950° there was created a forced flow of CH₄ through graphite materials. As a result of more uniform shutting of pores during treatment there was observed an increase of absolute weight gain compared to treatment in conditions of natural diffusion. Research of microstructure of graphite materials showed that in forced flow precipitation of C occurs throughout the sample.

TITLE: Sealing of porous graphitic carbon materials with pyrolytic carbon during the process of their thermal conditioning in an atmosphere of natural gas

SOURCE: Khimicheskaya promyshlennost', no. 11, 1964, 8-13

TOPIC TAGS: graphite, pyrolytic carbon, carbon/ARV graphite, TR 60/500 furnace, EPV2 11 potentiometer, PI 50 graphite

ABSTRACT: Sealing of porous graphitic carbon materials with pyrolytic carbon during heat treatment in natural gas was experimentally investigated. Synthetic carbon (type ARV, pores 0.6-9.0 micron, 25% porous, apparent density 1.5 g/cm³, specific area 0.58 m²/g) was placed in a TR-60/500 electric furnace (controlled by an EPV2-11 potentiometer ± 30) and was subjected to either forced filtration or external flow of natural gas (81.2% CH₄, 4.0% C₂H₆, 1.4% C₃H₈, 0.53% C₄H₁₀, 0.17% CO₂, 12.7% N₂). Forced filtration with natural gas or a gas mixture (15 and 30% H₂ by volume) was performed on cylinders (90 mm long, 20 mm outside diameter, 7 mm wall thickness) at 900, 950 and 1000C located as shown in Fig. 1a on the Enclosures.

Card 1/62

L 23020-65

ACCESSION NR: APL049567

3

External gas flow (165 ml/min) was applied to 20-mm diameter, 90-mm long cylinders located in different diameter tubes as shown in Figs. 1b and 1c on the Enclosures. The results of the experiments are shown in Figs. 2, 3, and 4 on the Enclosures. It was found that the properties of the pyrolytic carbon and the sealing effectiveness depended strongly on the free space above the surface of the specimens (see Fig. 3 on Enclosures); at a minimum free space above the specimen, the carbon formation at the surface was on the order of 10^{-5} - 10^{-6} g/cm² min; materials with apparent densities of less than 1.0 g/cm³ could be sealed significantly by this method; increasing the carbon formation rate decreased the properties of the carbon covering. The macrokinetic rate constant for the thermal conversion of methane to carbon on a porous graphite surface for temperatures of 900-1000C was found to be

$$k_p = 2.5 \cdot 10^{10} \exp(-78000/RT),$$

"A Case of Lethal Poisoning with Tofranil"

Sofia, Suvremenna Meditsina, Vol 17, No 12, 1966, p 1026

Abstract: Descriptions of acute poisoning with tofranil are seldom encountered in the world literature. The authors observed a case of lethal poisoning after a child 1 yr 4 mos old had swallowed approximately 35 tablets (875 mg) of this drug. The clinical symptoms comprised trembling of the face musculature, eyelids, and lips, loss of consciousness changing to coma, uninterrupted clonicotonic spasms, inhibition of the activity of the respiratory center (apnea), lowered body temperature, tachycardia, and cyanosis of the lips. The reaction of the pupils to light was retained. The child died seven hours after swallowing the drug.

TITLE: Peculiarities of the luminescence spectra of organic molecules under intense stimulation

SOURCE: Optika i spektroskopiya, v. 16, no. 3, 1964, 545-547

TOPIC TAGS: luminescence, luminescence reabsorption, pulse excitation, flash excitation, corcnene, benzophenone, Michler ketone, methacrylate, triplet-triplet transitions, organic molecule luminescence

ABSTRACT: The present investigation was undertaken in view of the current interest in the spectral characteristics of substances in the range of high stimulating light intensities when the population of the higher levels of the optical centers becomes high. Under such conditions, which are obtainable through use of intense flashtube illumination, triplet-triplet transitions may occur. However, there is only one paper in the literature reporting observation of triplet-triplet emission (H. von Schuler and G. Arnold, Zs. Naturforsch., 16a, 1091, 1961), and this pertains to naphthalene vapor. Accordingly, the present work makes an investigation into a luminescence reabsorption associated with triplet transitions (triplet-triplet

ACCESSION NR: AP4020977

absorption) in benzophenone, coronene, Michler ketone, and some other organic molecules dissolved in polymethacrylate and cooled to -120°C in a special cryostat. The luminescence spectra were excited by the light flashes from a powerful IFK-2000 (infrared) flash tube with a UFS-2 (UV) filter and photographed by means of an ISP-51 spectrograph with 1) frontal excitation (to eliminate reabsorption) and 2) side excitation (condition favorable for reabsorption). The absorption spectra were recorded by means of an ISP-28 spectrograph with a simplified pulse photometer. The traces of the different spectra of the above-mentioned three compounds in methacrylate are reproduced. In each case there is some evidence of reabsorption. The experimental data indicate that under certain conditions triplet-triplet absorption in organic molecule systems may result in significant alteration of the luminescence spectra due to reabsorption, a fact that should be borne in mind in investigating luminescence spectra of organic systems. TITLE: Monoanis of Glutacondialdehyde (monoanily glutaronovogo dial'gida) I. Derivatives of Primary Aromatic Amines (I. Derivativy pervichnykh aromaticheskikh aminov)

PERIODICAL: Zhurnal obshchey Khimii, 1948, Vol. 20, Nr 6, pp. 1677 - 1681 (USSR)

ABSTRACT: Of the derivatives of primary amines only the dinitro-substituted ones were known (ref 1). One of the authors synthesized the corresponding aminederivatives and other primary aromatic amines (Refs 4,5). However, the nature of these compounds was not investigated in detail as their yields were too small. In order to investigate similar compounds more closely the authors elaborated a method of synthesis of the derivatives of aniline and of other amines; in some cases they obtained considerable yields, and the authors could investigate their condensability in aromatic amines and compounds containing active methyl groups. The condensation of the monoanis with aromatic amines was carried out under different conditions: in acetic acid in the presence of hydrochloric acid, in acetic anhydride in the presence of hydrogen chloride and in pyridine in the presence of hydrogen

Card 1/3

chloride. Only in the last mentioned case a color change occurred, which could be taken as an indication as to the nature of the process of reaction, however, no definite result could be achieved. The investigations carried out of the monoanils of glutacone aldehyde showed in any way that they are of amphoteric character. Their condensability with compounds having active methyl groups can serve as indirect proof of the structure of the obtained monoanils. Thus the monoanils of glutacone aldehyde are investigated as derivatives of aromatic amines. It was shown that the unsubstituted monoanil and the monoanils of glutacone aldehyde with nucleophilic substituents in the aromatic nuclei do not enter the condensation with aromatic amines. The condensation of some monoanils with the methoxide of 2-methylbenzthiazole was carried out, however, the structure of the initial products could not be determined. There are 2 tables and 7 references, 3 of which are Soviet.

TITLE: On the Structure and the Reinforcing Action of Colloidal Silicic Acid as Filler of Synthetic Rubber (O strukture i usilivayushchem deystvii kolloidnoy kremnekisloty kak napolnitelya sinteticheskogo kauchuka)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol. 119, Nr 6, pp. 1170 - 1173 (USSR)

ABSTRACT: This work investigates the character of the distribution of the colloidal silicic acid as representative of a new class of intensifiers in sodium-butadiene rubber. This test object also was chosen for the following reason: Of the same raw material and also by the same method, only varying of the conditions of the technological process, samples of colloidal silicic acid with essentially different reinforcing effect can be produced. From this the possibility of the comparison of active and inactive fillers results. For the performance of these experiments a series of samples of colloidal silicic acid with high, mean, and low

Card 1/3

On the Structure and the Reinforcing Action of

20-119-6-33/56

reinforcing action in rubber sorts of sodium-butadiene rubber was produced. The chemical composition of these samples practically was equal and they also differed only very little with regard to the specific surface, pH, and various adsorption characteristics. But the rubber mixtures produced on the base of sodium-butadiene rubber, which contain the samples mentioned have an essentially different structure of the mixture and also essentially different physical-mechanical properties of the vulcanisates. The degree of the structuring of the filler in the mixture is characterized by the lixivation coefficient which is determined by the share of the filler, which passes over into the basic solution, in its total content in the mixture. A diagram illustrates the dependence of the lixivation coefficient on the rate of filling for samples of colloidal silicic acid of the highest or lowest reinforcement coefficient resp. (active resp. inactive samples). The most active silicic acid is leached out much easier than the inactive one. The higher the lixivation coefficient is for a given system the stronger marked are also the strength properties of the vulcanisate.

Structure and properties of filled rubber mixtures. III.
 Mixtures of sodium-butadiene rubber with channel black.
 B. Dogalkin, K. Pechkovskaya, and M. Dashvskii.
Kolloid. Zhur. 10, 357-68(1948). — The elec. resistivity R of
 mixts. of butadiene rubber (I) with C black (II) (av.
 particle size 35 μ , most frequent particle size 20 μ) is
 decreased 10-fold by good mixing. When the wt. ratio
 (r) II:rubber increases from 0.2 to 0.4, R decreases from
 1.8×10^9 ohm-cm. to 1.8×10^8 , while further increase of
 r to 0.6 lowers R to 1.5×10^8 only. Ohm's law is valid
 in all mixts. Increase of r from 0.2 to 0.6 increases d
 from 1.070 to 1.242 and lowers the swelling in EtOH +
 PhMe. Presumably at $r < 0.2$, II particles do not touch
 each other; between $r = 0.2$ and 0.4 they form chains,
 and above $r = 0.4$ they gradually fill the space between
 the chains. Stearic acid (5% of I) slightly increases R
 and slightly decreases the swelling ability of I + II.
 Nonvulcanized mixts. of I 100, II 60, stearic acid 2.5,
 Rutwax 5, mercaptobenzothiazole 1.8, ZnO 5, and S 1.5
 parts, have R of 1.5×10^8 . Vulcanization at 143°
 reduces R to 4.4×10^8 . Vulcanized rubbers of the above
 compo., except for II, have residual elongation, power loss,
 and heat formation at 40° deformation increasing with r ,
 while elasticity and plasticity are smaller the greater r is.
 The total relative elongation has a max. at $r = 0.2$.
 Tear resistance, abrasion resistance, and tensile strength
 have a max. at $r = 0.4$, i.e. when the II chains are fully
 formed.

Khim. i Khim. Prilozh. i Resiny*, 1959, p. 120-23. In contrast with channel black mixes, carbon black chain structures do not occur in two-component mixes with furnace or lamp black. Addition of these blacks to a toluene solution of rubber gives insignificant structural viscosity even with high concentrations of black. In the solid mix and in solution the chain structures occur through the addition of stearic acid in contents of about 50 ml black to 100 g of raw rubber, they are shown by electro-conductivity in solid mixes and structural viscosity in the solutions. In all cases in unvulcanized mixes the specific electrical resistivity depends upon the voltage, which indicates direct contact between the parts of the black structure. A continuous black structure is formed in mixes with not less than 50 ml of furnace or 60 ml of lamp black only after vulcanization. The physico-mechanical properties of the vulcanizates change as the filling rises, according to a curve with a maximum (tensile strength) or a monotonic curve (modulus, hardness, plasticity). The maximum of tensile strength occurs with about the same amount of filler as the formation of a continuous black structure.

RINARDI. *Industria del Caucci e Chimica Novesima e Vecina*, 1976, p. 141-42. Electron replica micrographs show that in mixes of sodium-butadiene rubber or of smoked sheet with less than 25 ml channel black to 100 g rubber, the distribution of different sizes of particle or aggregates of carbon black is non-uniform. As the black content increases the distribution becomes more uniform; these mixes are characterized by discrete distributions of the aggregates and by a chain structure. As the amount of filler increases the number and length of chains grows. Mixes with 25 to 40 ml black and above are characterized by a chain structure formed of the primary black particles and aggregates. In vulcanised sodium-butadiene mixes the size of the aggregates, whether discrete or linked in chains is increased in comparison with the aggregates in the unvulcanised mix. It was not possible to determine the distribution of black in vulcanised mixes of plasticised smoked sheet, as the presence of black in the mix was not evident in the electron micrograph. Tire Ind. 1950, No. 2. C black suspensions in H₂O,
E-1001, or folicum were dispersed by supersonic vibrations
and observed in an electron microscope. Sections of loaded
rubber were coated with collodion, which in turn was coated
with Cr, or with Me methacrylate, which in turn was coated
with SiO₂. Channel C blacks (D) form chains whose parti-
cles range from 250 to 400 Å; Ener I samples prove to be
better as fillers. In mixts of Land rubber, E is not well dis-
persed, but the dispersion is improved by adding sulfur
acid, mercaptobenzothiazole, etc. Chain carbons consist
of particles of 500-900 Å, and form chains when mixed with
rubber. Thermal C blacks are very polydisperse (0.1-1.5)
and do not agglomerate in rubber. I. I. Lukerman

TITLE: Electron microscopic investigation of latex gel structures

SOURCE: Kolloidnyy zhurnal, v. 26, no. 1, 1964, 72-75

TOPIC TAGS: latex gel, latex film, structure, syneresis, drying, vulcanization, electron microscope, polychloroprene latex, tensile strength, stretch, shrinkage

ABSTRACT: Electron microscopic investigation of gels and films obtained by ionic deposition of polychloroprene latex showed that they have a continuous globular structure which is retained throughout all stages of the technological process—syneresis, drying and vulcanization. Partial coalescence takes place during syneresis and drying, increasing the mean size of the globules and causing the system to become more homogeneous. This results in an increase in the tensile strength and relative stretch. Vulcanization does not cause breakdown of the globular structure, but the average size of the globules decreases, apparently due to

1781. Changes in carbon black structures in vulcanized rubbers under the influence of repeated deformation and heating. *B. A. Droganov and K. A. Pechkovskaya. 'Sovetskoe i Ucheno-issledovatel'skoe'*, 1959, p. 53-57. In rubbers containing active blacks there are formed structures whose development and change with fatigue may be followed from the specific d.c. electrical resistivity, ρ . With carbon-carbon bonds the strength of the current I is expressed by $I = eV$, where V is the voltage and e a constant; in other cases $I = eV^n$, where $n > 1$. The change of ρ with temperature is expressed as $\rho = \rho_0 e^{\alpha/T}$

where α being the temperature; $\alpha > 0$ if raising T leads to destruction of the carbon black structure, and $\alpha < 0$ in the opposite case. The authors investigated ρ , n , α and $n\alpha/n_0$, where n_0 is the factor for the rubber in its original state. The approximation of n to 1 after the effect of stress or temperature shows that the carbon-carbon bonds are stronger than the carbon-rubber bonds. With repeated deformation and heating, the weaker bonds are gradually destroyed, and in the remaining structures the proportion of stronger bonds increases. With active carbon blacks the C-C bonds are stronger than the C-rubber bonds, with furnace blacks the two types of bond are of approximately equal strength, while with the semi-active blacks the C-C bonds are the weaker. The conference discussion is reported. This paper incorporates much experimental data and conclusions which have appeared previously (cf. *Rubb. Abstr.*, 1963, abs. 256 and 2638).

PM
WT

where d is the optical density of the suspension. This index depends on three basic properties of the carbon black; it increases with increasing specific surface area of the black and decreases as the degree of structuration increases, and also with increasing reamination of the surface. A method is worked out for determining this index, comprising the dispersion of carbon black in water by means of ultrasonic oscillation from a magnetostrictive vibrator. The resulting dispersions will stand dilution to concentrations permitting the sufficiently accurate determination of the optical density. The tensile strength of vulcanizates containing carbon black increases with the increase in the colorimetric index of these carbon blacks. The considerable scatter which is observed is explained by the influence of many other factors upon the mechanical strength of the vulcanizates, and also in some cases by the known non-uniformity of certain carbon blacks. The colorimetric index is recommended as a value which, in conjunction with others, gives a more exact and objective picture of the quality. There are 5 references.

TITLE: Use of electron microscopy for evaluation of carbon black distribution in rubber mixtures

SOURCE: Zavodskaya laboratoriya, v. 29, no. 8, 1963, 968-970

TOPIC TAGS: electron microscopy, carbon black distribution, rubber mixture, tear surface, cast, aggregate

ABSTRACT: Carbon black samples were prepared from the same batch, deaggregated on a vibrator, hydrated, or treated with graphite, and then incorporated into rubber. Investigation by an electron microscope was conducted on ultra-thin slices of the rubber as well as on casts made from torn surfaces of vulcanized rubber discs. The cast method was preferred, since in making slices it was necessary to encase a small band of the sample rubber in methylmetacrylate with benzoyl peroxide as polymerization initiator, followed by incubation at 49C. This resulted in a distortion of the original structure of the sample. It was found that an increase in the surface activity of channel carbon black by

Card 1/2

hydration results in an increase in the average size of the carbon black aggregates, while pre-treatment with graphite has the opposite effect, due to a lowering of its surface activity. Orig. art. has: 2 pictures and 1 table.

TITLE: Comparative study of the physicochemical and technical
properties of test samples of disperse furnace blacks of the
HAF type

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 23, 1961, 560, abstract
23P347. (Tr. N.-i. in-ta shin. prom-sti, sb. 5, 1960, 68-80)

TEXT: The results of a comparative study of the properties of test
samples of disperse furnace blacks (DB) of the HAF type from liquid raw
material and import fillblack O are presented. The increased adsorptive
surface of the DB blacks and their higher oxygen content can retard the
vulcanization process and sometimes diminish strength of vulcanizate.
As to dispersity, the DB blacks, produced under semi-industrial conditions
from liquid raw material, are not inferior to the best blacks of type HAF.
The most important physicochemical and chemical properties of the DB
blacks are given along with the electrical conductivity, internal friction.

TITLE: Methods for determining the specific surface area of semi-reinforcing and reinforcing blacks for the technical control of black production

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 23, 1961, 560, abstract 23P348. (Tr. N.-i. in-ta shin. prom-sti, sb. 5, 1960, 81-94)

TEXT: A description is given of three methods for determining the specific surface area of semireinforcing and reinforcing blacks. The specific adsorption surface is obtained by the method of adsorption of I_2 , the geometrical specific surface by the calorimetric method, and the method of Deryagin provides a specific surface close to the adsorption specific surface. All of the three methods furnish conditional values for the specific surface, are simple, and can be used for the first technical control of the dispersity of blacks in industrial laboratories. TITLE: The classification of carbon blacks for the production of rubber

PERIODICAL: Kauchuk i rezina, no. 4, 1961, 47-48

TEXT: Prior to the Second World War two types of carbon black were manufactured in the Soviet Union: channel gaseous and lamp carbon black. By 1956 six different types were produced, viz. furnace, jet burner, thermal and anthracene carbon black. In connection with the forthcoming revision of the **ГОСТ** - GOST 7885-56, the introduction of a new, stricter classification of the carbon blacks is being considered. In the recommended classification the name of the carbon blacks takes into account the use of the raw material. A number is added to the letter designation if more than one type of carbon black is produced by one method from the same raw material. The first letter designates the method of the carbon black production **К** - (K), for channel, **П** (P) for furnace, and **Т** (T) for thermal. The second letter is associated with the type of the raw material. ✓

TITLE: Reinforcement of rubber in latex. 7. Electron microscopic
examination of filled latex mixtures

PERIODICAL: Kolloidnyy zhurnal, v. 23, no. 4, 1961, 462-463

TEXT: This report was made at the tret'ye Vsesoyuznoye soveshchaniye
po elektronnoy mikroskopii (Third All-Union Conference on Electron
Microscopy), Leningrad, October 1960. The second communication of this
series was published in Trudy II konferentsii po lateksu, Leningrad 1958.
The authors based their report on a paper by B. A. Dogadkin et al. (Kolloidn.
zh. 18, no. 5, 528, 1956) which shows that a reinforcing action of carbon
black in latex can be attained by adding a destabilizing substance (casein)
to latex. Here, this effect was studied under an 3M-100 (EM-100) electron
microscope having a magnifying power of approximately 20,000. Collodion,
quartz, or carbon replicas of the latex film, frozen in liquid nitrogen,
were prepared. It was found that 1) all latex films containing neither

B101/B215

Reinforcement of...

carbon black nor casein had globular structures. 2) Addition of casein changed the structure. Part of the globuli disappeared, and a granular structure formed. Casein removes the protective covering of the globuli, thus allowing the latter to form a continuous polymer phase and to interact with carbon black. The contact area between polymer and carbon black is increased and, thus, causes reinforcement. 3) If the non-vulcanized, filled film was rolled, the last globuli disappeared. 4) Carbon black also had a destabilizing effect upon latex, although to a smaller extent than casein. Films with carbon black without casein contained less but larger globuli. 5) The number of globuli was reduced in the presence of carbon black and casein. [Abstracter's note: The electron microscopic pictures are irreproducible.] There are 1 figure and 2 Soviet-bloc references.

TITLE: Electron-microscopic Investigations of Rubber Mixtures
and Their Basic Components (Elektronno-mikroskopich-
eskoye issledovaniye rezinovykh smesey i ikh osnovnykh
komponentov)

PERIODICAL: Kauchuk i rezina, 1959, Nr 3, pp 12 - 18 (U SR)

ABSTRACT: Most interesting results of electron-microscopic invest-
igations were obtained when analysing natural and synthetic
rubbers (Refs 3 to 8). It was possible to determine the
sol and gel fractions of natural rubber, the sulphur-
structure which is characteristic for rubbers and the
relation between the dimensions of spherical components
and the molecular weight of the rubber, as well as the
characteristics of the secondary structure of crystallising
rubbers. During the present investigations the authors
used a modified electron microscope EM-100 with a 0.25 mm

Card 1/3

Electron-Microscopic Investigations of Rubber Mixtures and Their
Basic Components

diaphragm (0.05 mm diaphragm aperture) which made it possible to increase the resolving power of the microscope from 100 to 30 Å. Details of the preparation of samples from rubber solutions as well as from hard rubbers are given and electron-microscopic tests were carried out on them. Figure 1 shows photographs of a natural rubber film sample; Figure 2 a colloidal replica with an unplasticised butadiene-styrene rubber surface; Figure 3 a quartz replica of an unfilled natural rubber vulcanisate; Figure 4 a quartz replica of unfilled vulcanisate prepared from natural and sodium-butadiene rubber. In all cases the degree of magnification is quoted. Further tests were carried out on various types of activated carbon black. A generator with a special vibrator (15 cycles/second) was used for dispersing the carbon black in alcohol or in toluene (Figure 5). Figures 6 to 9 show micro-photographs of four activated carbon blacks, and a table gives characteristics of their degree of dispersion. Formulae for calculating the average

Card 2/3

SOV/138-59-5-4/16

Electron-Microscopic Investigations of Rubber Mixtures and Their Basic Components

diameters are given. Special channel black is used in the manufacture of various types of ink. It is characterised by a high degree of dispersion, and a lesser degree of coarseness than normal channel black. Anthracene black resembles furnace black to a greater degree than channel black. This is confirmed by comparative tests on rubbers containing the two types of carbon black; rubbers containing anthracene black as fillers showed a higher rate of vulcanisation and higher moduli. There are 9 figures, 1 table and 17 references, of which 5 are English, 4 German and 8 Soviet.

TITLE: Electron-microscopic Investigations of Vulcanized Products of Natural and Synthetic Rubber (Elektronnomikroskopicheskoye issledovaniye vulkanizatorov natural'nogo i sinteticheskikh kau-chukov)

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1959, Vol 23, Nr 6, pp 725 - 728 (USSR)

ABSTRACT: In the introduction a number of papers (Refs 1-7) are listed, in which the structure of rubber products vulcanized by means of electron microscopes were investigated by means of the replica method. Two further papers (Refs 8,9) are mentioned, in which the thermodynamical compstibility of rubber was investigated, which showed the importance of cohesion energy. It was also found that in mixtures of two different kinds of rubber, their properties do not behave additively. In the present paper the authors describe the carrying out of electron-microscopic work with vulcanized products which have one or two types of rubber as a basis. In the first part of this paper the investigations of pure natural rubber and of three synthetic rubbers are dealt with. For this purpose, the method of quartz-replica
